Chapter 6
System Engineering

- Computer-based system

- System engineering process

- "Business process" engineering

- Product engineering

Computer-based System

Introduction

- Software engineering occurs as a consequence of system engineering
- System engineering may take on <u>two</u> different forms depending on the application domain
    - <u>"Business process" engineering</u> – conducted when the context of the work focuses on a business enterprise
    - <u>Product engineering</u> – conducted when the context of the work focuses on a product that is to be built
- Both forms bring order to the development of computer-based systems
- Both forms work to allocate a role for computer software and to establish the links that tie software to other elements of a computer-based system

System

- System (Webster)
  - A set or arrangement of things so related as to form a unity or organic whole
  - A set of facts, principles, rules. etc., … to show a logical plan linking the various parts
  - A method or plan of classification or arrangement
  - An established way of doing something such as a method or procedure

Computer-based System

- Defined: A set or arrangement of elements that are organized to accomplish some predefined <u>goal</u> by processing information
- The goal may be to support some business function or to develop a product that can be sold to generate business revenue
- A computer-based system makes use of system elements
- Elements constituting one system may represent one macro element of a still larger system
- Example
  - A factory automation system may consist of a numerical control machine, robots, and data entry devices; each can be its own system
  - At the next lower hierarchical level, a manufacturing cell is its own computer-based system that may integrate other macro elements
- The role of the system engineer is to <u>define the elements</u> of a specific computer-based system in the context of the overall hierarchy of systems

Computer-based System (continued)

- A computer-based system makes use of the following four system <u>elements</u> that combine in a variety of ways to transform information
  - **Software**: computer programs, data structures, and related work products that serve to effect the logical method, procedure, or control that is required
  - **Hardware**: electronic devices that provide computing capability, interconnectivity devices that enable flow of data, and electromechanical devices that provide external functions
  - **People**: Users and operators of hardware and software
  - **Database**: A large, organized collection of information that is accessed via software and persists over time
- The uses of these elements are described in the following:
  - **Documentation**: Descriptive information that portrays the use and operation of the system
  - **Procedures**: The steps that define the specific use of each system element or the procedural context in which the system resides

System Engineering Process

System Engineering Process

- The system engineering process begins with a <u>world view;</u> the business or product domain is examined to ensure that the proper business or technology context can be established
- The world view is refined to focus on a specific <u>domain of interest</u>
- Within a specific domain, the need for <u>targeted system elements</u> is analyzed
- Finally, the <u>analysis, design, and construction</u> of a targeted system element are initiated
- At the world view level, a very <u>broad</u> context is established
- At the bottom level, <u>detailed</u> technical activities are conducted by the relevant engineering discipline (e.g., software engineering)

"Always design a thing by considering it in its next larger context –
a chair in a room, a room in a house, a house in an environment,
and environment in a city plan"

System Engineering Hierarchy

World View

Domain View

Element View

Component View
System Modeling
(at each view level)

- Defines the <u>processes</u> (e.g., domain classes in OO terminology) that serve the needs of the view under consideration
- Represents the <u>behavior</u> of the processes and the assumptions on which the behavior is based
- Explicitly defines intra-level and inter-level <u>input</u> that form <u>links</u> between entities in the model
- Represents all linkages (including output) that will enable the engineer to better understand the view
- May result in models that call for one of the following
  - Completely automated solution
  - A semi-automated solution
  - A non-automated (i.e., manual) approach

Factors to Consider when Constructing a Model

- Assumptions
  - These reduce the number of possible variations, thus enabling a model to reflect the problem in a reasonable manner
- Simplifications
  - These enable the model to be created in a timely manner
- Limitations
  - These help to bound the maximum and minimum values of the system
- Constraints
  - These guide the manner in which the model is created and the approach taken when the model is implemented
- Preferences
  - These indicate the preferred solution for all data, functions, and behavior
  - They are driven by customer requirements

Optimization of some of these factors may be mutually exclusive

System Modeling with UML

- The Uniform Modeling Language (UML) provides diagrams for analysis and design at both the system and software levels
- Examples
  - Use case diagrams
  - Activity diagrams
  - Class diagrams
  - State diagrams

"Business Process" Engineering

Business Process Engineering

- "Business process" engineering defines architectures that will enable a business to use information effectively
- It involves the <u>specification</u> of the appropriate computing architecture and the <u>development</u> of the software architecture for the organization's computing resources
- <u>Three</u> different architectures must be analyzed and designed within the context of business objectives and goals
  - The <u>data architecture</u> provides a framework for the information needs of a business (e.g., ERD)
  - The <u>application architecture</u> encompasses those elements of a system that transform objects within the data architecture for some business purpose
  - The <u>technology infrastructure</u> provides the foundation for the data and application architectures
    - It includes the hardware and software that are used to support the applications and data
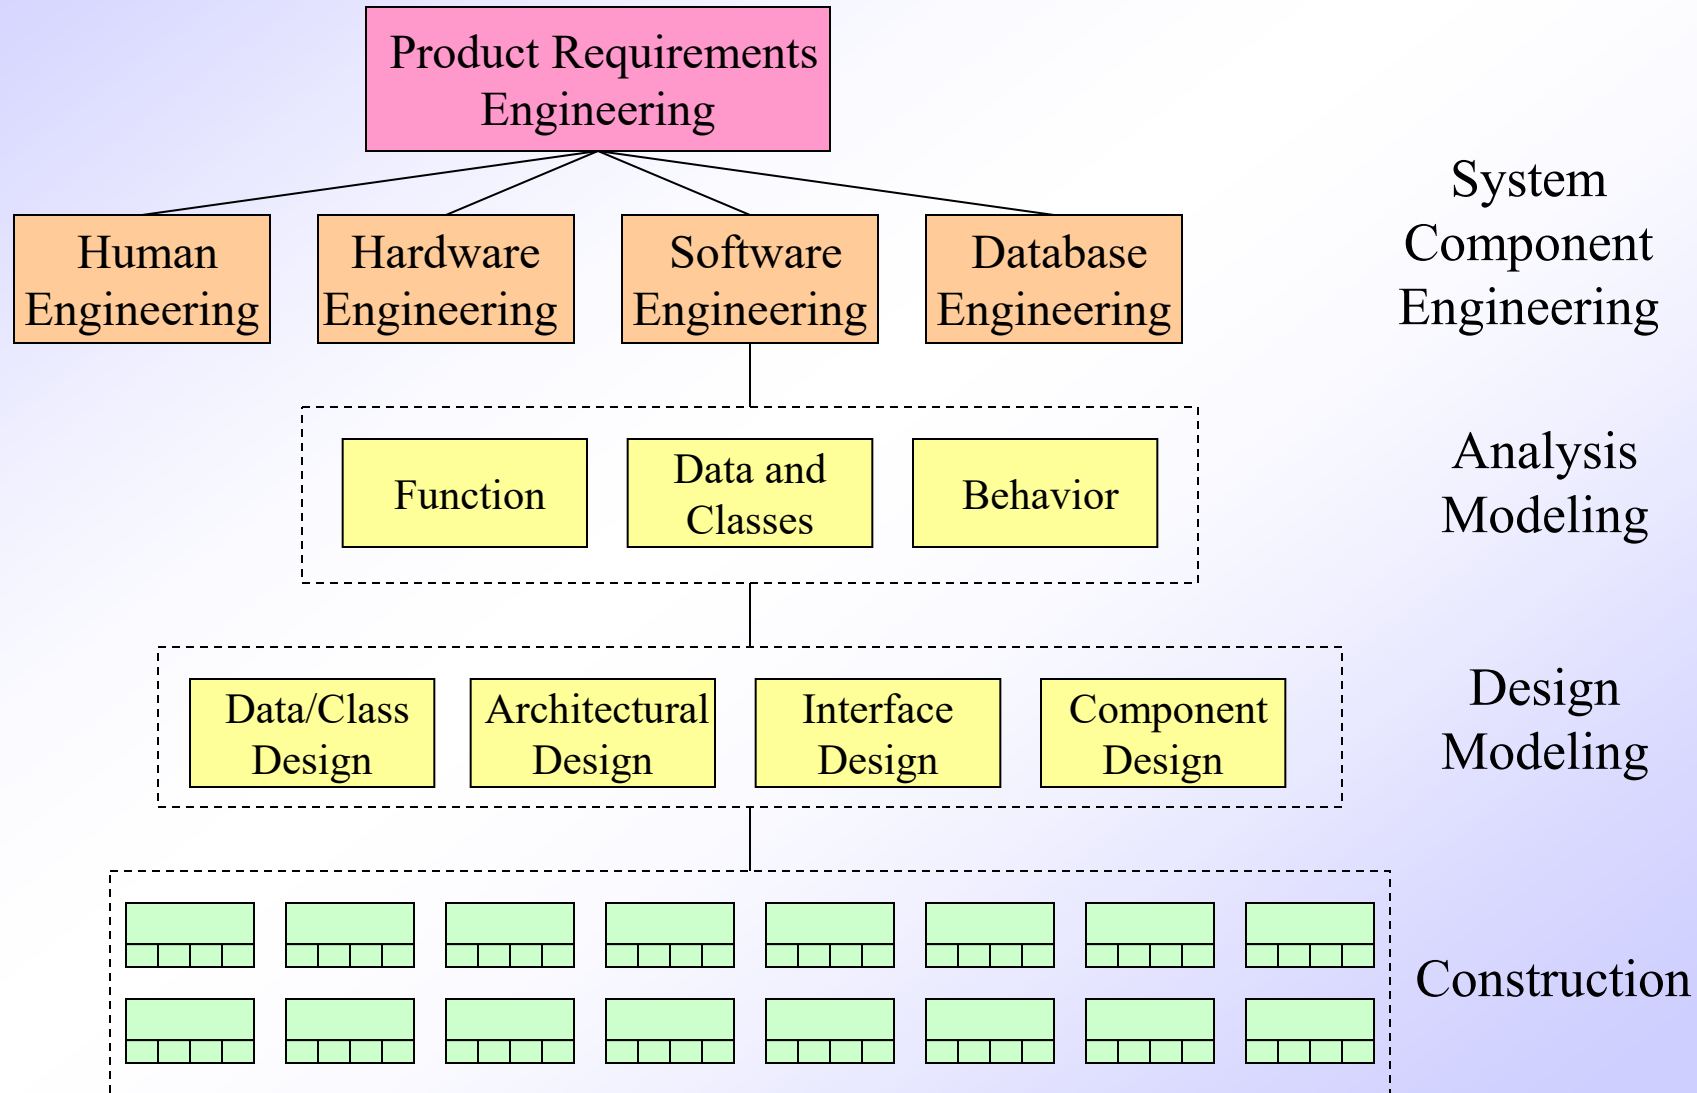

Product Engineering

Product Engineering

- Product engineering translates the customer's desire for a set of defined capabilities into a working product
- It achieves this goal by establishing a <u>product architecture</u> and a <u>support infrastructure</u>
  - Product architecture components consist of people, hardware, software, and data
  - Support infrastructure includes the technology required to tie the components together and the information to support the components
- <u>Requirements engineering</u> elicits the requirements from the customer and allocates function and behavior to each of the four components
- <u>System component engineering</u> happens next as a set of concurrent activities that address each of the components separately
  - Each component takes a domain-specific view but maintains communication with the other domains
  - The actual activities of the engineering discipline takes on an element view
- <u>Analysis modeling</u> allocates requirements into function, data, and behavior
- <u>Design modeling</u> maps the analysis model into data/class, architectural, interface, and component design

Product Engineering Hierarchy

System Component Engineering

- Product Requirements Engineering
  - Human Engineering
  - Hardware Engineering
  - Software Engineering
  - Database Engineering

Analysis Modeling
- Function
- Data and Classes
- Behavior

Design Modeling
- Data/Class Design
- Architectural Design
- Interface Design
- Component Design

Construction
